

Skeleton Root

001_path.sh → t01_example

002_tarExe.sh → t01_example

-- defining a hardening primitive that is stronger than “export an env-var”;

-- creating hardened tarballs -- first experiment

1. The t01_ is an example that was verified to make sure the code performs as expected;
2. Tarball name: 20260205091502SIL.tar requires a backup directory /home/<user>/xLibs;
3. Prerequisite:
 - (a) <skeleton>/003_list.txt contains all files that are scheduled to be patched by 001_path.sh;
 - (b) <skeleton>/dev/t01_cmn.sh is in ready to be patch state, prior creating the tarball;
 - (c) <skeleton>/docs are updated with files pertinent to this experiment;
4. Create tarball: cd /<skeleton> sudo ./002_tarExe.sh

Note: 002_tarExe.sh expects a custom path by modifying:

TAR_lib="/home/<user>/xLibs" # hardcoded path to xLibs

-- untar to any path must read /home/pleb/xSIL20260203/docs/tar_untar.html

sudo mkdir -p <Destination>

3. Restore clone(source.tar) to destination(project-root-path)

sudo tar -xzf /path2/xLibs/20260205091502SIL.tar \

--strip-components=1 -C /path2/destination/2026020509SIL

then, cd /path2/destination/2026020509SIL and sudo ./001_path.sh

this reminder note is for GVF developers and it is not an abstract any-longer.

Paradigm: <source> <Destination>

sudo mkdir -p <Destination> \

&& sudo tar -xzf <source> --strip-components=1 -C <Destination>

cd <Destination>

sudo ./001_path.sh

cd dev && cat t01_cmn.sh

sudo chmod +x t01_cmn.sh

sudo ./t01_cmn.sh

test completed

Create tarball (restore point):

cd <Destination>

sudo ./002_tarExe.sh

the tarball is in the library /path/xLibs/20260205101146SIL.tar

To continue working on same devs:

cd <Destination>

sudo ./001_path.sh && cd dev

...
